

Is Beryllium heavy?

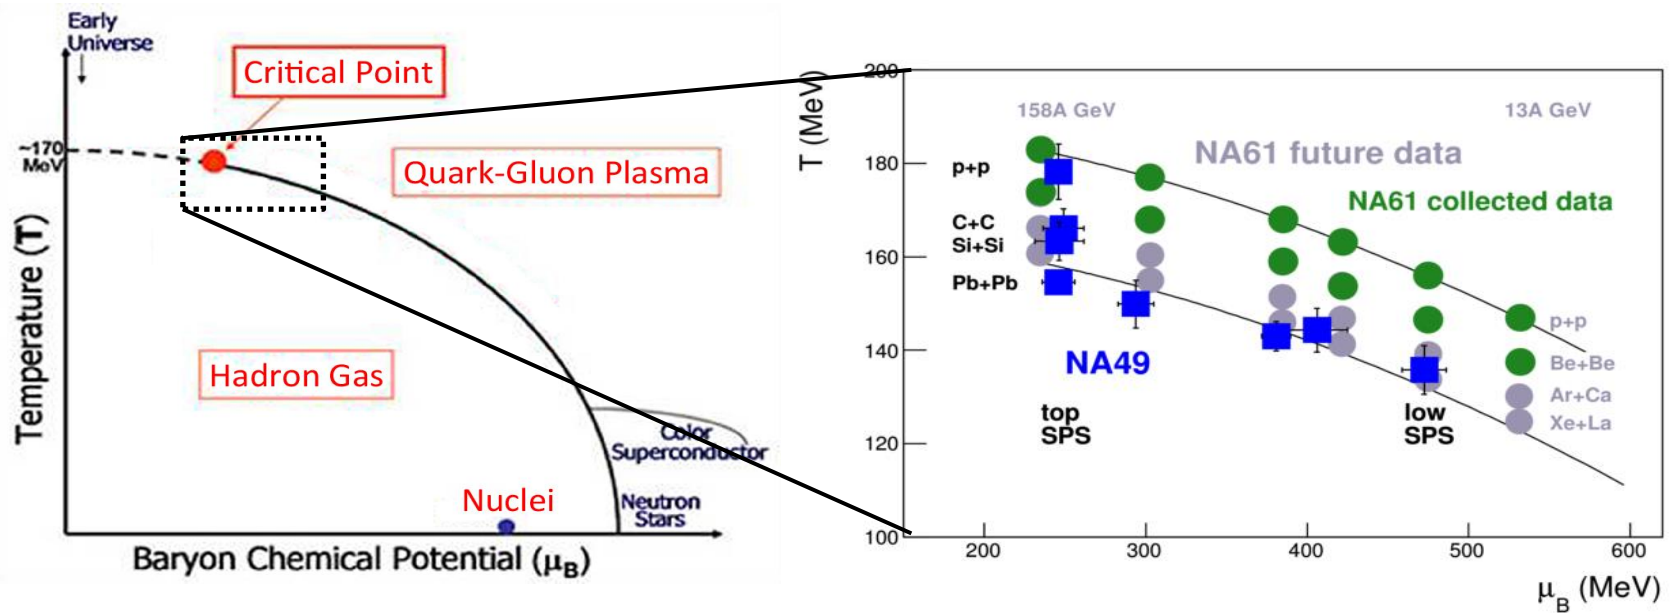

The first results on Be+Be collisions

NA61/SHINE (SPS Heavy Ion and Neutrino Experiment)

Inelastic cross section ${}^7\text{Be}+{}^9\text{Be}$

Beryllium interaction example

$$P_{\text{int}}^{S4} = \left(\frac{N_{\text{Interactions}}}{N_{\text{beams}}} \right)_I - (1 - P_{\text{int}}^0) \left(\frac{N_{\text{Interactions}}}{N_{\text{beams}}} \right)_R$$

P_{int}^0 – approximate probability of interaction in target

P_{int}^{S4} – total probability of interaction in target

Inelastic cross section ${}^7\text{Be}+{}^9\text{Be}$

Bevalac point, Phys. Rev. Lett. **55** (1985) 2676.
Glauber (GLISSANDO, Kielce) Model, Comput.Phys.Commun. 180 (2009) 69.

Projectile Spectator Detector

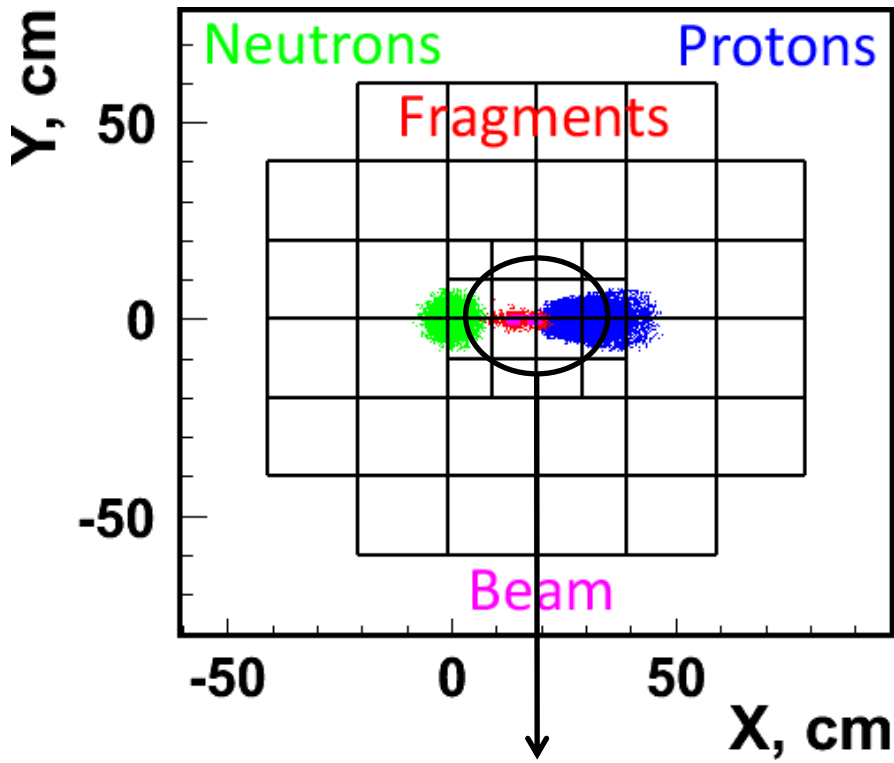

PSD during 2011 data taking
(40A, 75A and 150A GeV/c Be+Be)

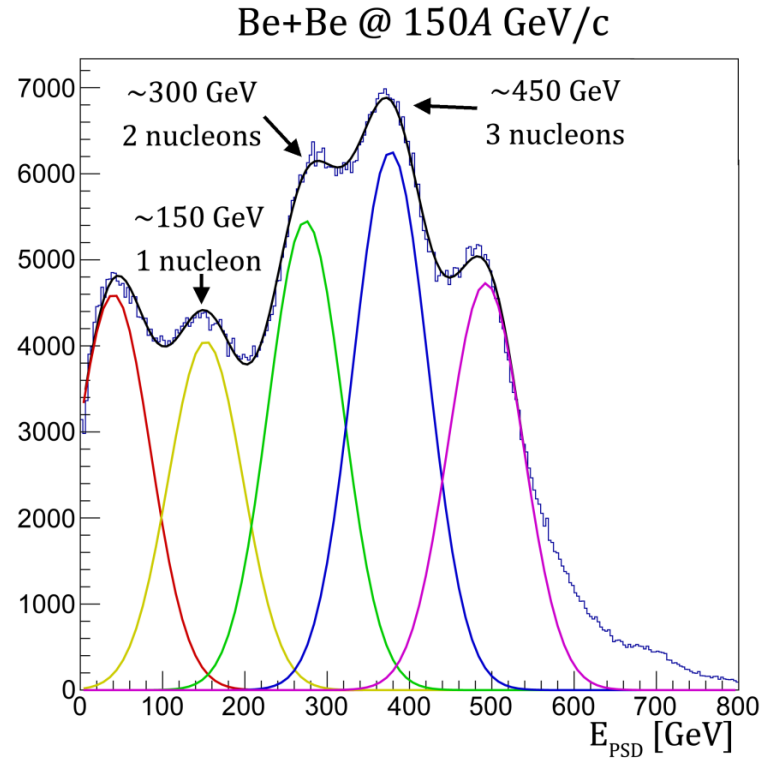

Spectators spatial distribution
on the PSD front face
for Be+Be at 150A GeV/c

PSD performance

Central modules

Energy spectrum from PSD central modules

One nucleon resolution!

PSD performance

Resolution calculated
for p, d, t, He, Be and Pb beams
at 40A, 75A, 80A and 150A GeV/c

Centrality Classes

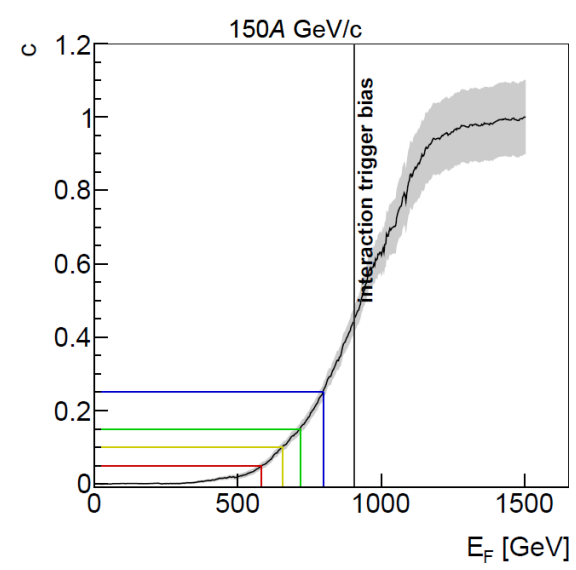

Semicentral collisions chosen by interaction trigger

- based on the energy deposited in the PSD,
- four centrality classes:

- centrality defined as percent of total inelastic cross section:

$$c(E_F) = \frac{1}{P_{int}^{S4}} \int_0^{E_F} P_{int}(E'_F) dE'_F.$$

P_{int}^{S4} – total probability of interaction in target

Is Beryllium heavy?

Compared to other metals by the density of the solid state
Beryllium is quite light

h^- method of π^- spectra determination

- Determination of negative hadrons spectra, corrected for geometrical acceptance, feed-down and detector effects,
- Correction of small (<10%) contribution from non-pion hadrons based on Monte-Carlo models (EPOS),
- The h^- method covers much larger region of phase-space than dE/dx or ToF identification.
- Details about the method were presented by Antoni Aduszkiewicz

Transverse momentum vs. rapidity spectra of π^- mesons

Beam Momentum

Centrality Class

40A GeV/c

75A GeV/c

150A GeV/c

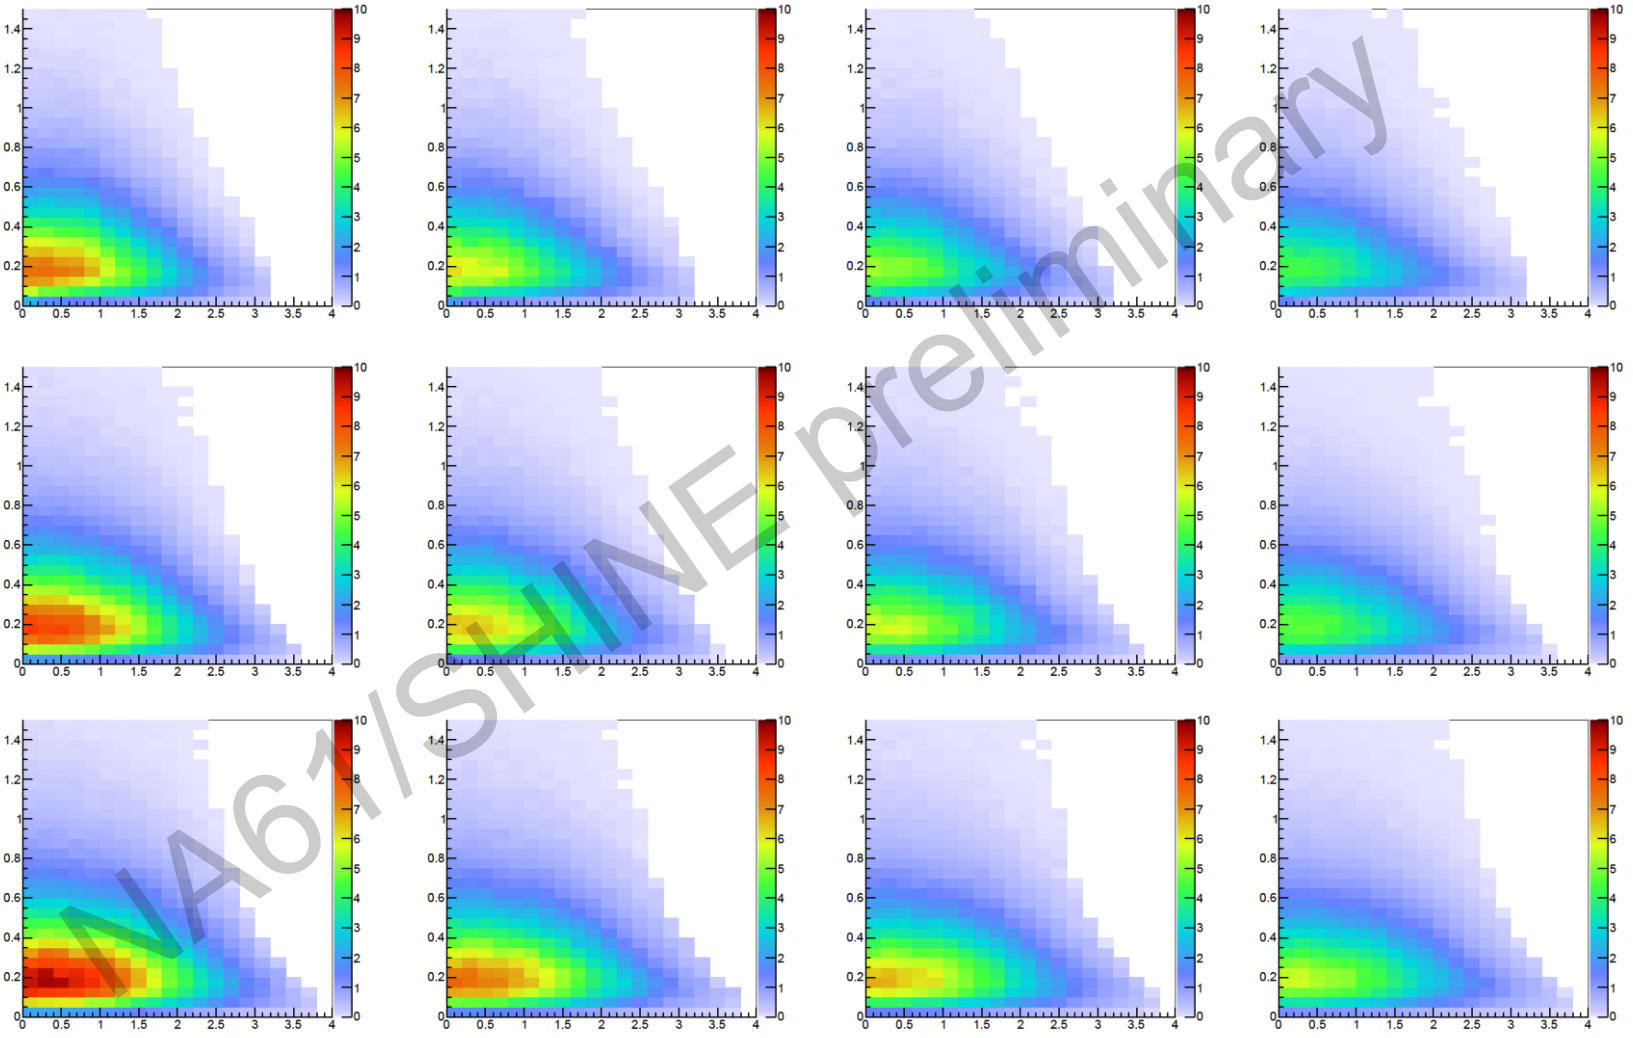

0 – 5%

5 – 10%

10 – 15%

15 – 25%

p_T [GeV/c]

y

Transverse mass spectra of π^- mesons

Convex shape of Pb+Pb and Be+Be spectra

p+p spectra exponential

$$\frac{dn}{dm_T} = A m_T \exp\left(-\frac{m_T}{T}\right)$$

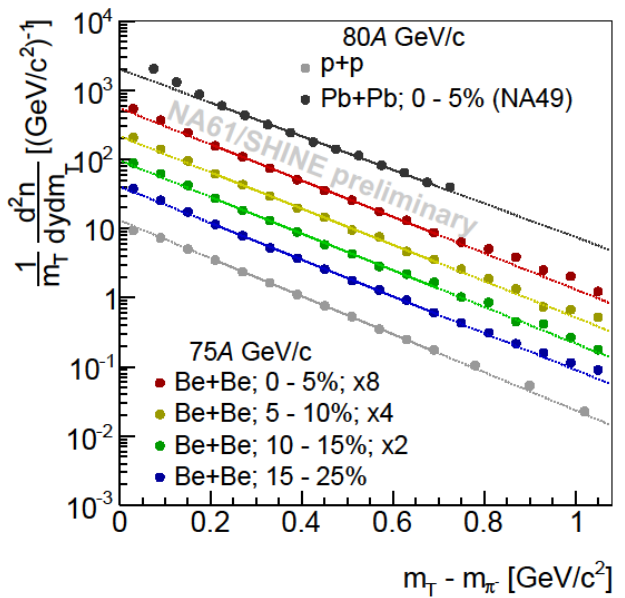

fitted in range $0.2 < m_T - m_\pi < 0.7 \text{ GeV}/c^2$

mid-rapidity ($0.0 < y < 0.2$)

Transverse mass spectra of π^- mesons

mid-rapidity ($0.0 < y < 0.2$)

Transverse mass spectra of π^- mesons

Inverse slope parameter T

Fitted in range
 $0.2 < m_T - m_\pi < 0.7 \text{ GeV}/c^2$

Inverse slope parameter of transverse mass spectra is significantly larger in Be+Be than in p+p

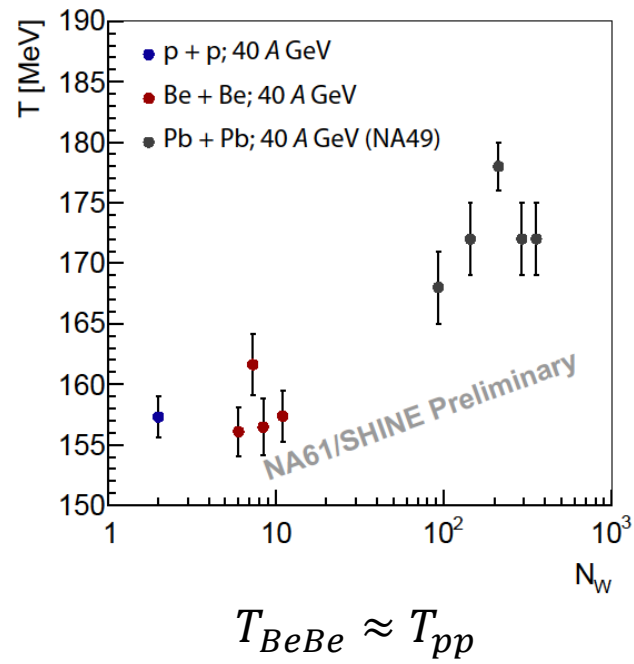

Possible evidence of transverse collective flow in Be+Be collisions

dE/dx identification will provide Kaon and Proton results soon.
Simultaneous fit to three particles types will give better answer regarding flow.

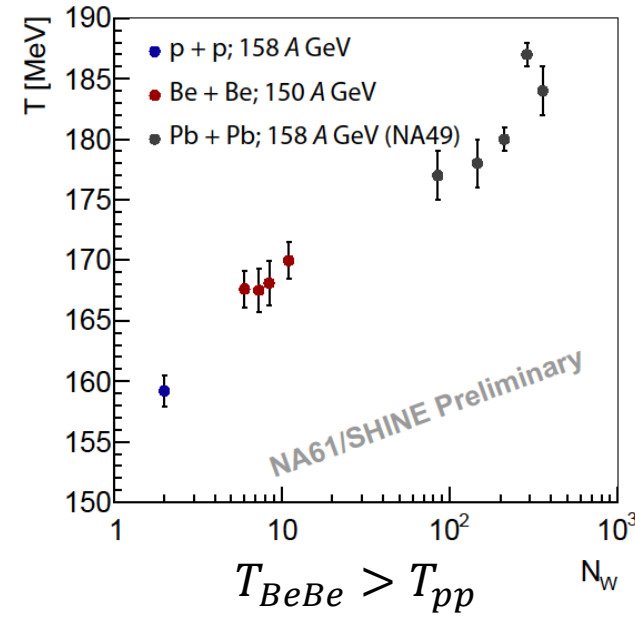

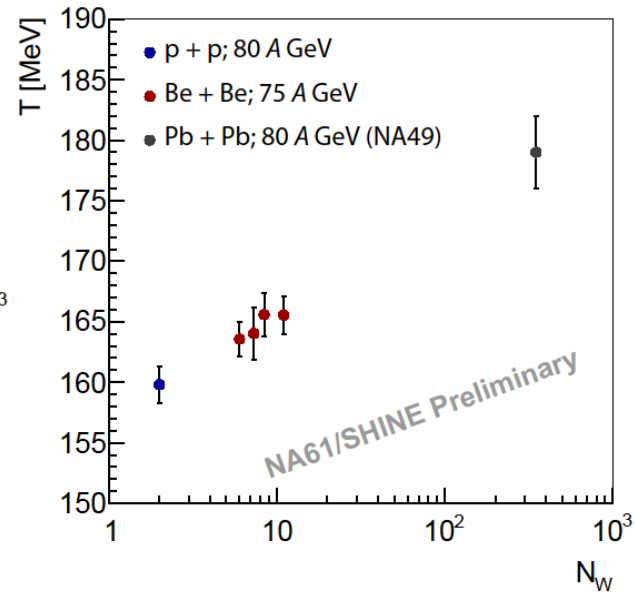

Transverse mass spectra of π^- mesons

Inverse slope parameter T

Inverse slope parameter in Be+Be changes with beam momentum

Number of wounded nucleons in Beryllium obtained by Glauber (Glissando) Model (not final)¹⁶

Transverse mass spectra of π^- mesons

Inverse slope parameter

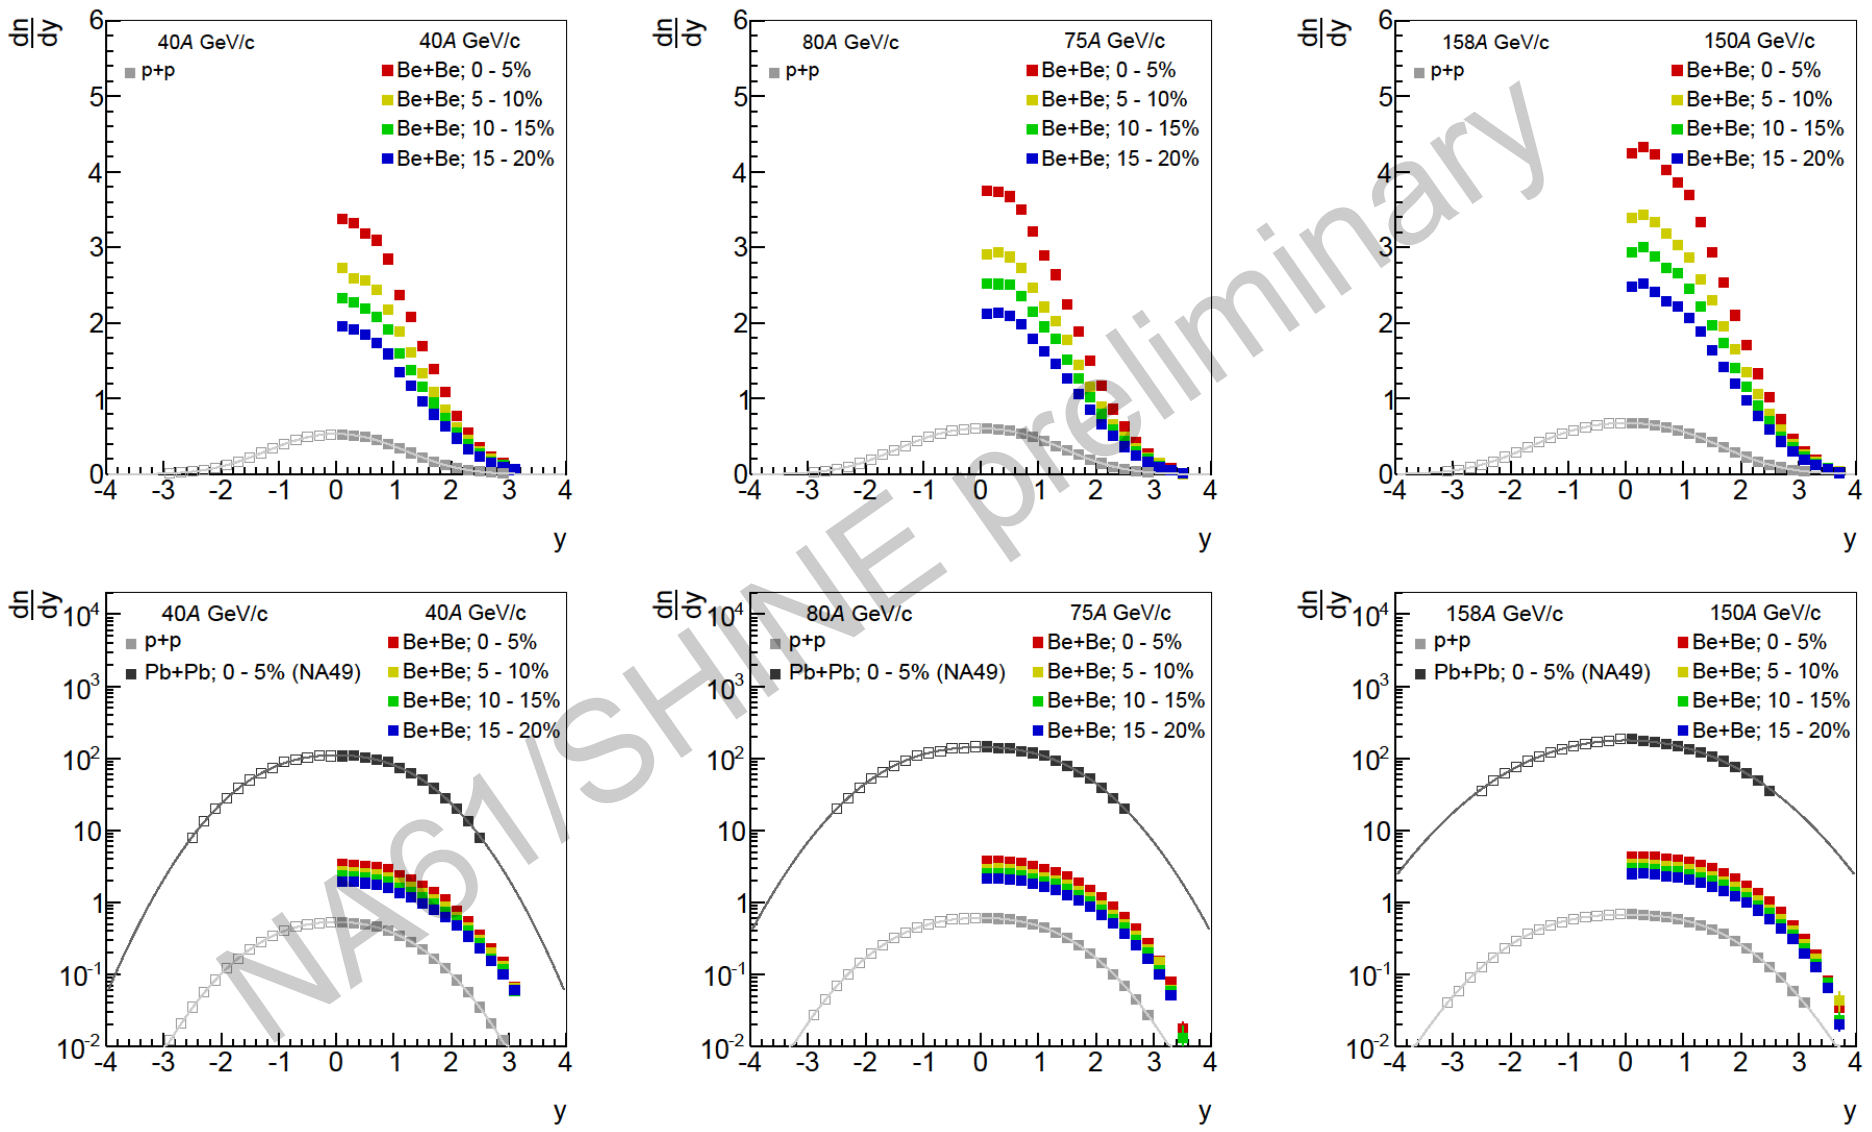

Beryllium looks heavy at 150A GeV/c!

Energy dependance of T parameter in Be+Be similar to Pb+Pb

Rapidity spectra of π^- mesons

Mean of rapidity distribution Asymmetric system

The rapidity distribution is shifted to the backward rapidity values due to target being heavier than projectile.

Based on EPOS Monte-Carlo simulations

Mean value of rapidity distributions
Centrality classes based on impact parameter

	7Be+9Be
0 – 5%	-0.048(3)
5 – 10%	-0.039(3)
10 – 15%	-0.035(3)
15 – 25%	-0.028(2)
25 – 100%	-0.014(2)

Mean of rapidity distribution Forward energy trigger bias

Centrality classes based on forward energy.
Restriction on wounded nucleons from projectile but not from target.
The mean of the rapidity distribution shifted to the forward region.

Based on EPOS Monte-Carlo simulations

Summary

- First results from Be+Be collisions measured by NA61/SHINE were presented,
- Determination of inelastic cross-section for 7Be+9Be collisions at 13A to 30A GeV/c,
- Negative pion spectra in central 7Be+9Be collisions at 40A to 150A GeV/c,
- Interesting behaviour of inverse slope parameter of transverse mass spectra in 7Be+9Be,
- Extrapolation to 4π yields under investigation (although not obvious due to forward energy trigger bias).

THANK YOU

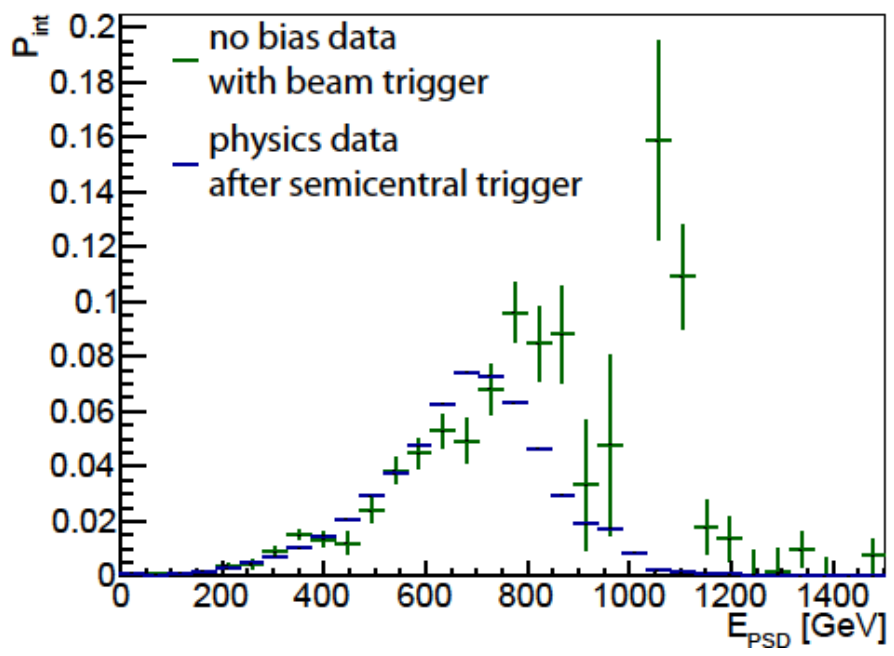

emil.aleksander.kaptur@cern.ch

Centrality Method

Calculation of probability of interaction as in cross section determination, but in every PSD energy bin (green points).

Integral of $P_{\text{int}}(E_{\text{PSD}})$ is the percent of cross section.

Centrality classes defined by percent of total inelastic cross section based on forward energy. Edges of classes determined as:

$$(5 \pm 0.9)\% - (10 \pm 1.2)\% - (15 \pm 1.5)\% - (25 \pm 2.1)\%$$
